Conclusions

Dans le cadre d'une classification binaire de données linéairement séparables, nous savons que le perceptron est adapté. C'est donc sans trop de surprise que l'on constate qu'un seul neurone suffit pour venir à bout de la classification de cette distribution de points.

Le meilleur choix de variables est X_1 et X_2 .

La fonction d'activation la plus adaptée est la fonction Linear.

La diminution du learning rate permet de faire converger le modèle plus rapidement.

Distribution Ou Exclusif

Distribution Ou Exclusif

Visualisation de la distribution

Observation

Chaque classe est répartie dans deux cadrans. La séparation n'est pas linéaire.

Distribution Ou Exclusif

Visualisation de la distribution

Observation

Chaque classe est répartie dans deux cadrans. La séparation est de forme hyperbolique.

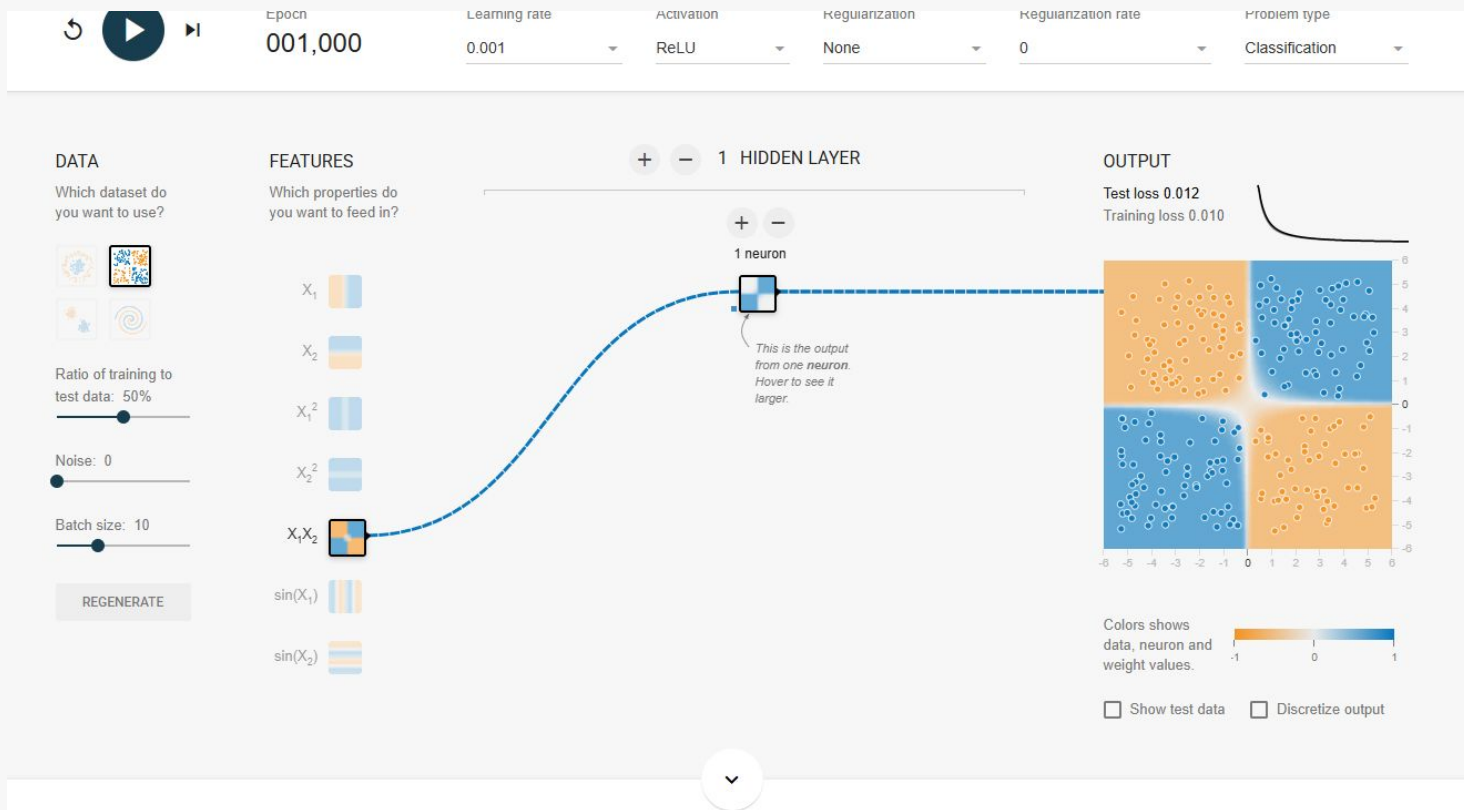

Les variables les plus susceptibles de permettre au réseau de neurones de converger sont donc X_1X_2 .

Conclusions

Le meilleur choix de variables est X_1X_2 .

La fonction d'activation les plus adaptées sont les fonctions Tanh et Linear qui donnent des résultats équivalents.

Le nombre de neurones optimal est 4.

La diminution du learning rate permet de faire converger le modèle plus rapidement.
